---

---

---

---

---

---

---

---

---

---

---

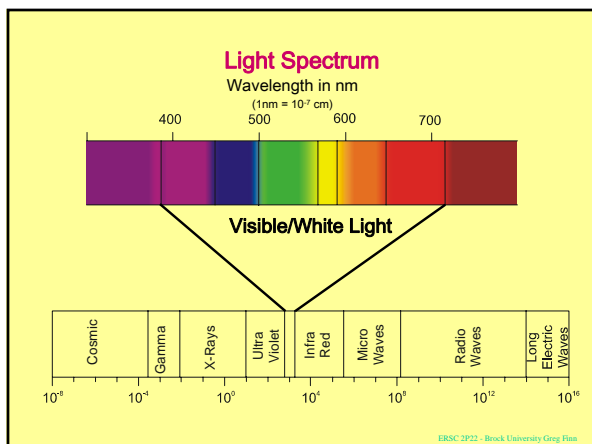

---

---

---

---

---

---

---

---

### Theory of Light

- Two complimentary theories to explain how light behaves and the form by which it travels:
  - Particle Theory
    - \_\_\_\_\_
  - Wave Theory
    - \_\_\_\_\_
    - Waves have \_\_\_\_\_ and \_\_\_\_\_ properties
      - \_\_\_\_\_ **Radiation**

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Theory of Light

- Wave theory explains polarization, reflection, refraction and interference
- The basis of Optical Mineralogy

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

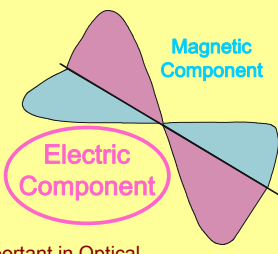

---

---

---

---

### Components of a Light Ray

The electric and magnetic components:

- 1) vibrate at \_\_\_\_\_ to each other, and
- 2) at \_\_\_\_\_ to the Direction of Propagation

Important in Optical, referred to as the Vibration Direction of the Light Ray

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Light

- Behaviour of light in minerals results from the \_\_\_\_\_ of the **Electric Component**, or vector, with the electric character of the \_\_\_\_\_ and the chemical \_\_\_\_\_ holding the mineral together
- Vibration direction of the electric vector is \_\_\_\_\_ to the direction of propagation of the light ray

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

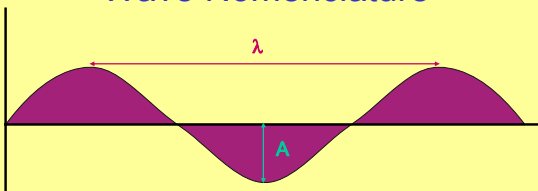

---

---

---

---

### Wave Nomenclature

Wave is travelling from left to right with a velocity (V)

The wavelength ( $\lambda$ ) is the distance between successive wave crests

The amplitude (A) is the height of the wave

The frequency is the number of wave crests per second which pass a reference point. Frequency is expressed as cycles per second or Hertz (Hz).

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Wave Nomenclature

- Light waves are described in terms of:
  - Velocity (V)
  - Frequency (F)
  - Wavelength ( $\lambda$ ), where:

$$F = \frac{V}{\lambda}$$

F is a constant and V of  $\lambda$  will vary to maintain F

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

---

---

---

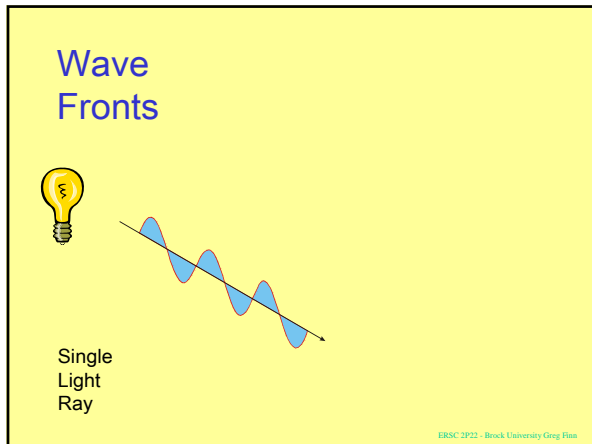

---

---

---

---

---

---

---

---

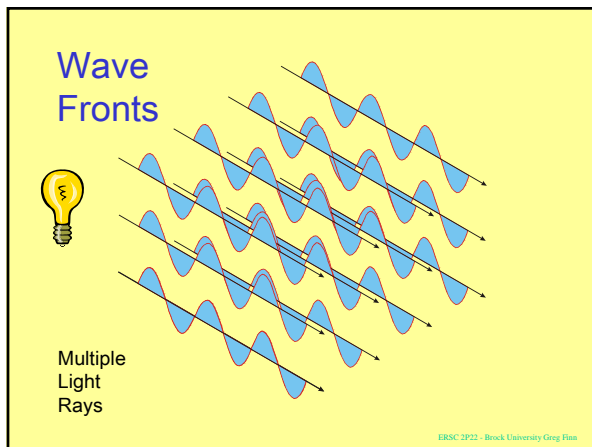

---

---

---

---

---

---

---

---

---

---

---

---

---

### Isotropic Materials

For Isotropic Materials  
 The **Wave Normal** and the **Direction of Propagation** of the light rays are \_\_\_\_\_ to each other and \_\_\_\_\_ to the **Wave Front**

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

---

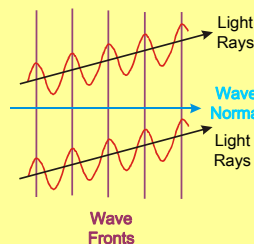

---

---

---

### Anisotropic Materials

For Anisotropic Materials  
 The **Wave Normal** and the **Direction of Propagation** of the light rays \_\_\_\_\_.

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Isotropic vs. Anisotropic

<ul style="list-style-type: none"> <li>• Shows same velocity of light in all directions</li> <li>• Bonds are the same in all directions</li> <li>• Wave Normal and Direction of Propagation are parallel</li> <li>• Isometric minerals and volcanic glass</li> </ul>	<ul style="list-style-type: none"> <li>• Different velocity for light with direction</li> <li>• Bonds differ with direction</li> <li>• Wave Normal and Direction of Propagation are not parallel</li> <li>• Tetragonal, hexagonal, orthorhombic, monoclinic and triclinic systems</li> </ul>

## Properties of Light II

Continued

---

---

---

---

---

---

---

---

## Phase and Interference

- Light rays travelling along the same path in the same direction will \_\_\_\_\_ with each other
- **RETARDATION ( $\Delta$ )**
  - Represents the distance that one ray lags behind another
  - Measured in nanometres ( $\mu\text{m}$ ;  $1\mu\text{m} = 10^{-7}\text{cm}$ ) **OR** the number of wavelengths by which a wave lags behind another

---

---

---

---

---

---

---

---

### Phase and Interference

$\Delta = 1, 2, 3 \dots$  wavelengths

Waves **A** and **B** are \_\_\_\_\_ ( $\Delta = 1\lambda$ ), so that the waves constructively interfere and produce the resultant wave (**R**)

ERSC 3P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Phase and Interference

$\Delta = \frac{1}{2}, 1 \frac{1}{2}, 2 \frac{1}{2} \dots$  Wavelengths

Waves **A** and **B** are \_\_\_\_\_ ( $\Delta = (i + \frac{1}{2}\lambda)$ ). The amplitudes of waves **A** and **B** are equal, but opposite, they cancel each other (destructive interference) and the resultant wave (**R**) has zero amplitude.

ERSC 3P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Phase and Interference

$\Delta =$  Intermediate Number of Wavelengths

Waves **A** and **B** will be partially:

- 1) **IN PHASE**, with the interference being partially constructive,
- and;
- 2) **OUT OF PHASE** with the interference being partially destructive.

The resultant wave (**R**) is the sum of the two waves

ERSC 3P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Phase and Interference

- In the previous examples the rays were vibrating in the same plane  
(This makes the visualization simpler)
- If the two rays vibrate at some angle to each other they will still interfere and produce a resultant wave, whose vibration direction can be determined mathematically

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Perception of Colour

- Human eye can discriminate different wavelengths of light – why we see colours
  - Red light has a wavelength of 660 nm
- Light of all one wavelength is termed \_\_\_\_\_ light and is perceived as the colour associated with that wavelength

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Perception of Colour

- Light of more than one wavelength is termed \_\_\_\_\_ light
- When all of the visible spectrum is present we 'see' \_\_\_\_\_
- The colour that we perceive results from a combination of wavelengths being \_\_\_\_\_ / \_\_\_\_\_ by the material

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

## Interaction of Light and Matter

---

---

---

---

---

---

---

---

### Transmitted Light

- In a vacuum light travels at  $3 \times 10^{10}$ cm/sec ( $3 \times 10^{17}$ nm/sec)
- In any other medium (minerals) it is \_\_\_\_\_ down, due to the interaction of the electric vector of the light with the electronic configuration of the mineral
- To maintain a constant frequency, the \_\_\_\_\_ of light must also change:

$$F = \frac{v}{\lambda}$$

---

---

---

---

---

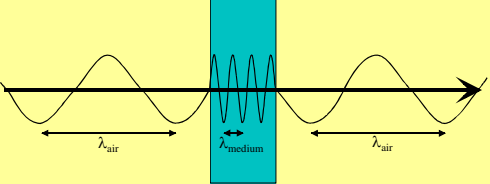

---

---

---

### Transmitted Light

- Light is slowed (velocity drops) when it enters another medium. To maintain  $F$ , as a constant, the wavelength must shorten as well.

The diagram illustrates a light wave passing through a medium. On the left, the wave is in air with a wavelength labeled  $\lambda_{\text{air}}$ . It then enters a blue rectangular medium where the wavelength is labeled  $\lambda_{\text{medium}}$  and is visibly shorter. After exiting the medium, the wavelength returns to  $\lambda_{\text{air}}$ . The frequency of the wave remains constant throughout.

---

---

---

---

---

---

---

---

### Transmitted Light

- When a light ray strikes the boundary between two substances at an oblique angle the light may be:

- 
- 
- 

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Reflection

angle of incidence = angle of reflection  
 $\angle i = \angle r$

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Refraction

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Refraction of Light

From: <http://hyperphysics.phy-astr.gsu.edu/hbase/geomopt/optpic/brokpens.jpg> ERSC 3P22 - Brock University Greg Finn

---

---

---

---

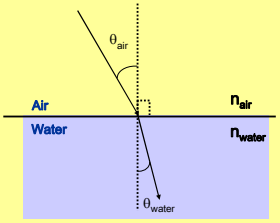

---

---

---

---

### Refraction

A measure of how effective a material is at bending light is termed the \_\_\_\_\_ (n)

ERSC 3P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Index of Refraction

- Index of Refraction – **n**  

$$n = \frac{V_{vac}}{V_{medium}}$$
- Most minerals have **n** values in the range 1.4 to 2.0
- A \_\_\_\_\_ **n** or **RI** indicates a \_\_\_\_ velocity for light in that medium
- A \_\_\_\_\_ **n** or **RI** indicates a \_\_\_\_ velocity for light in that medium

ERSC 3P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### How much will light bend?

- Use Snell's Law

$$\frac{\sin \theta_a}{\sin \theta_w} = \frac{n_w}{n_a}$$

- $n_a = n_{vac} = 1$ ,  $n_w = 1.33$
- If  $\theta_a = 45^\circ$
- Then  $\theta_w = 32^\circ$
- Equation holds for either direction

ERSC 3P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Light Absorption and Colour

- The colour of a mineral is the colour of light that is \_\_\_\_\_ absorbed on transmission or reflection
  - A white object looks white because it reflects essentially all the visible light spectrum
  - A black object absorbs all wavelengths of light
  - A clear mineral transmits essentially all the visible spectrum
  - A mineral is coloured because it selectively absorbs certain wavelengths of light and transmits or reflects the remaining light to your eye

ERSC 3P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Light Absorption and Colour

- The perceived colour is dependant on which \_\_\_\_\_ are transmitted to the eye, and how the eye interprets these wavelengths
- The perceived colour of a mineral is dependant on the colour of the \_\_\_\_\_ light
- An object that is white in sunlight, will appear blue in blue light, red in red light, etc. as these are the only wavelengths of light transmitted to the observer

ERSC 3P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Light Absorption and Colour

- At the atomic scale, the colors of light absorbed by a mineral are dependant on the \_\_\_\_\_ between the \_\_\_\_\_ vector of the light and the natural resonances of the \_\_\_\_\_ around each atom
  - If the frequency of light is different than the natural resonance, then the light is transmitted
  - If the frequency of light is nearly the same as the natural resonance than the light is absorbed

ERSC 3P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Polarization of Light

- All this introductory material on the nature and behaviour of light brings us to the most critical aspect of optical mineralogy:

\_\_\_\_\_

ERSC 3P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Polarization of Light

ERSC 3P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Polarization of Light

**Circular Polarization**  
The light ray passes through a filter which has two preferred vibration directions, such that:  
 $\Delta = \frac{1}{4}\lambda$

**Elliptical Polarization**  
The light ray passes through a filter which has two preferred vibration directions, such that:  
 $\Delta \neq \frac{1}{4}\lambda$

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

---

---

### Polarization by Reflection

A single ray of light vibrating in all directions.

The reflected ray, with a single vibration direction, parallel to the reflecting surface.

Reflecting Surface  $i = r$

Reflected light is completely polarized only when the angle between the reflected and the refracted ray is  $90^\circ$

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

---

---

### Polarization by Selective Absorption

Only the ray which vibrates parallel to the permitted vibration direction (which in this case is the c-axis) passes through the polar, all vibration directions are absorbed.

Direction of Polarization is parallel to the c crystallographic axis.

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

---

---

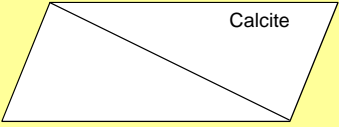

---

---

---

---

### Polarization by Double Refraction via Nicol Prism

Calcite

The Nicol Prism – constructed of calcite, first must cut the calcite on the diagonal, and then glue the two pieces back together with Balsam ( $n=1.537$ ).

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

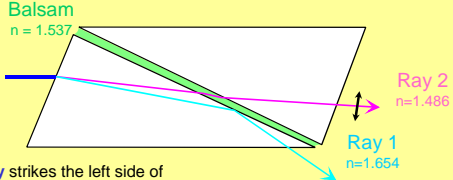

---

---

---

---

### Polarization by Double Refraction

Balsam  
 $n = 1.537$

Ray 2  
 $n = 1.486$

Ray 1  
 $n = 1.654$

A light ray strikes the left side of the calcite and is split into two rays – Ray 1 and Ray 2, each with different refractive indices. Ray 1 undergoes total internal reflection when it reaches the Balsam, because the angle of incidence is greater than the critical angle.

Ray 2 passes through the first piece of calcite into the Balsam and then into the second piece of calcite, being refracted at each interface and retains its polarization direction upon exiting the calcite.

ERSC 2P22 - Brock University Greg Finn
