

## Interference Figures

### Uniaxial Minerals

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

## Interference Figures

Uses:

- Means by which uniaxial and biaxial minerals can be \_\_\_\_\_ from each other, and
- For determining the \_\_\_\_\_ of a mineral, specifically for uniaxial minerals whether:
  - $n_o > n_e$  **Optically Negative**, or
  - $n_o < n_e$  **Optically Positive**

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

## Interference Figures

To obtain and observe an interference figure:

1. With high power, focus on a mineral grain free of cracks and inclusions
  2. Flip in the auxiliary condenser and refocus, open aperture diaphragm to its maximum
  3. Cross the polars
  4. Insert the Bertrand lens, look down the microscope tube
- Will not see the grain, but the interference figure, which appears on the top surface of the objective lens

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

### Uniaxial Interference Figure

- For Uniaxial minerals three types of interference figures are produced:
  - Centred Optic Axis Figure (OA vertical)
  - Off Centred OA Figure (OA) inclined)
  - Flash Figure (OA horizontal)
- Each figure reflects the orientation of the indicatrix within the mineral grain

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

### Optic Axis Figure

- If the optic axis is \_\_\_\_\_, the mineral grain will exhibit 0 birefringence and remain black, or nearly black, on rotating the stage
- Resulting figure produced is a \_\_\_\_\_
- Consists of a centred black \_\_\_\_\_ superimposed on \_\_\_\_\_ bands of \_\_\_\_\_

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

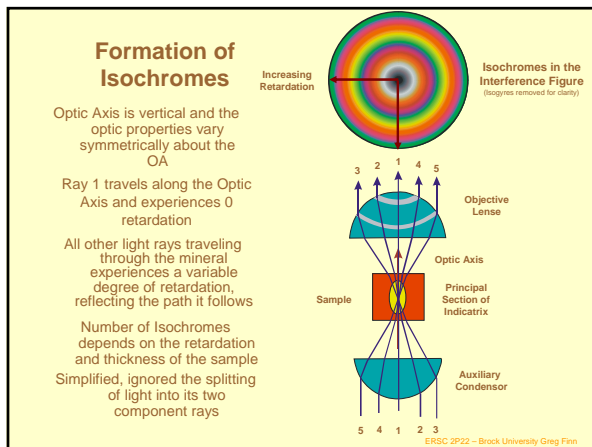

---

---

---

---

---

---

---

---

---

---

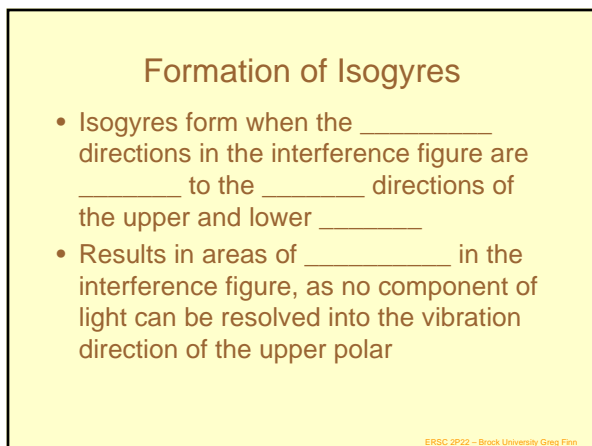

---

### Formation of Isogyres

#### Vibration Directions on the Indicatrix Surface

Vibration directions for each ray of light passing through the mineral can be determined (we did this earlier)

If we do this for an infinite number of rays then:

All **Ordinary Rays** vibrate parallel to lines analogous to lines of latitude

All **Extraordinary Rays** vibrate parallel to lines analogous to lines of longitude

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

### Formation of Isogyres

#### Vibration Directions in the Interference Figure

The mineral, with its indicatrix oriented such that the Optic Axis is vertical, with a convergent cone of light

Light rays, each of which is split into  $\epsilon$  and  $\omega$  rays, pass through the objective lens and the vibration directions for each ray can be projected onto the upper surface of the objective lens

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

### Formation of Isogyres

---

---

---

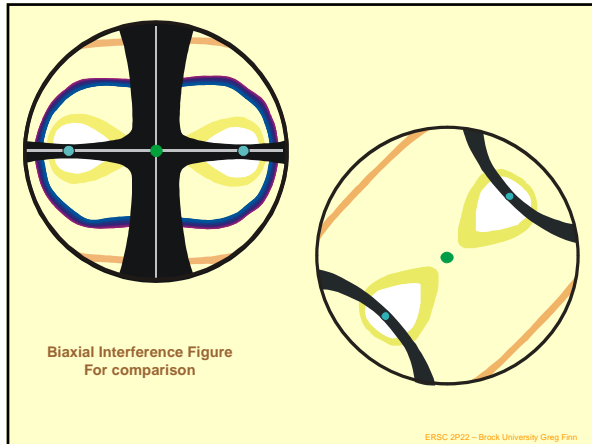

---

---

---

---

---

---

---

---

---

---

### Determining the Optic Sign

- Once the interference figure has been:
  - Obtained
  - Identified as to whether it is uniaxial vs. biaxial, and
  - The orientation of the optic axis in the figure is determined **then**
  - The optic sign can be determined using the accessory plate(s)
- Why determine the optic sign?

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

### Determining the Optic Sign

- The Optic Sign tells whether the **Ordinary Ray** is the \_\_\_\_ or \_\_\_\_ ray exiting the mineral
- Optically Positive**
  - $\omega$  = fast ray
  - $\epsilon$  = slow ray
- Optically Negative**
  - $\omega$  = slow ray
  - $\epsilon$  = fast ray

ERSC 2P22 - Brock University Greg Finn

---

---

---

---

---

---

---

---

## Determining the Optic Sign

To determine the optic sign:

1. Obtain an optic axis interference figure, (Look for a grain that exhibits the lowest interference colour for the mineral)
2. Note the interference colour of the mineral
3. Insert the accessory plate (become familiar with the gypsum plate)
4. Observe the change in interference colours
  - In two quadrants the colours increase
    - Colours move up the colour chart
  - In two quadrants the colours decrease
    - Colours move down the colour chart
5. Look in the NE quadrant of the interference figure

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

---

---

## CLARIFICATION!!!!

Quadrants of the Field of View

Quadrants of the Interference Figure

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

---

---

Uniaxial Optic Axis Figure – Optic Sign Determination

Few to no isochromes

$\epsilon$  ray = slow ray

Using the Gypsum Plate

Optically Positive

In the NE quadrant of the Interference Figure the interference colours **increase**, move up the colour chart, from **grey** to **blue**

Overall this is an increase in total retardation, as the slow ray of the mineral is parallel to the slow ray in the accessory.

Therefore the  $\epsilon$  ray is the slow ray

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

---

---

Uniaxial Optic Axis Figure – Optic Sign Determination

Few to no isochromes

Using the Gypsum Plate

**Optically Negative**

Case II

In the NE quadrant of the Interference Figure the interference colours **decrease**, move down the colour chart, from **grey** to **yellow**

Overall this is a decrease in total retardation, as the fast ray of the mineral is parallel to the slow ray in the accessory.

Therefore the  $\epsilon$  ray is the fast ray

$\epsilon$  ray = fast ray

---

---

---

---

---

---

---

---

Uniaxial Optic Axis Figure – Optic Sign Determination

Using the Gypsum Plate

**Optically Positive**

Case I

**Optically Negative**

Case II

$\epsilon$  ray = slow ray

$\epsilon$  ray = fast ray

---

---

---

---

---

---

---

---

### Optic Sign Determination

- If the interference figure exhibits few to no \_\_\_\_\_, the gypsum plate is used to determine the sign,
- Insert the plate and note the change in colour in the NE quadrant, of the figure, from grey to:
  - **Blue** (positive) or
  - **Yellow** (negative)

ERSC 2P22 – Brock University Greg Finn

---

---

---

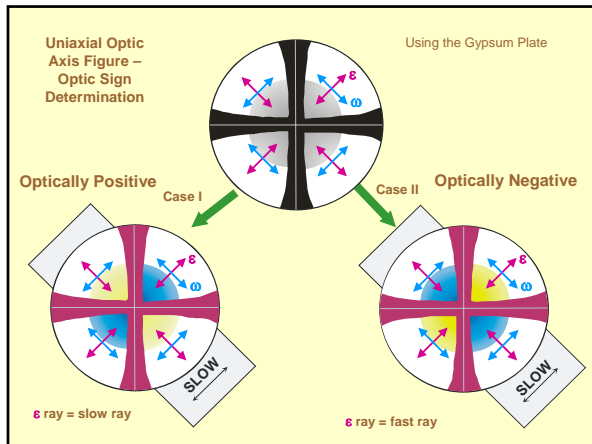

---

---

---

---

---

---

---

---

---

---

---

---

---

### Quartz Wedge

- If the interference figure exhibits \_\_\_\_\_ isochromes then the quartz wedge is used to determine the optic sign
- Inserting the quartz wedge results in the \_\_\_\_\_ of the isochromes about the isogyre
- The direction of movement assists in determining the optic sign

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

### Quartz Wedge

- In quadrants where the fast ray of the mineral is parallel to the slow ray of the wedge, the isochromes move \_\_\_\_\_, as \_\_\_\_\_ order colours form at the melatope and displace \_\_\_\_\_ order colours
  - ε = fast ray
- In quadrants where the slow ray of the mineral is parallel to the slow ray of the wedge, the isochromes move \_\_\_\_\_, as \_\_\_\_\_ order colours replace \_\_\_\_\_ order colours
  - ω = slow ray

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

**Uniaxial Optic Axis Figure – Optic Sign Determination**

**Quartz Wedge** **Optically Positive**

Numerous Isochromes

Direction of movement of the isochromes as the wedge is inserted

**$\epsilon$  ray = slow ray**

In the NE and SW quadrants of the figure the isochromes move in  
In the NW and SE quadrants of the figure the isochromes move out

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

---

---

---

---

**Uniaxial Optic Axis Figure – Optic Sign Determination**

**Quartz Wedge** **Optically Negative**

Numerous Isochromes

Direction of movement of the isochromes as the wedge is inserted

**$\epsilon$  ray = fast ray**

In the NE and SW quadrants of the figure the isochromes move out  
In the NW and SE quadrants of the figure the isochromes move in

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

---

---

---

---

**Uniaxial Optic Axis Figure – Optic Sign Determination**

**Quartz Wedge** **Optically Positive**

Numerous Isochromes

**$\epsilon$  ray = slow ray**

Direction of movement of the isochromes as the wedge is inserted

**$\epsilon$  ray = fast ray**

**Optically Negative**

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

---

---

---

---

## Off Centred Optic Axis

- Produced when the optic axis is \_\_\_\_\_, and results in the interference figure no longer \_\_\_\_\_ in the field of view (FOV)
- Isogyres still form a cross, which will lie outside the FOV with the melatope at the centre

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

Vibration Directions on indicatrix surface

### Off Centred Optic Axis (at extinction)

The isogyre fattens as the distance from the melatope increases  
 The vibration direction of the:

- Ordinary ray** is tangential to the isochromes,
- Extraordinary ray** is radial, from the melatope

**Melatope** (point where the Optic Axis emerges, the centre of the cross) lies outside the FOV. Will only see a single isogyre in the FOV

Mineral, with its indicatrix oriented such that the Optic Axis is inclined to vertical, with a convergent cone of light

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

### Off Centred Optic Axis (on rotation)

Only one isogyre will be visible in the FOV at any time. As the stage is rotated the isogyre will sweep across the FOV, in the direction indicated, to be replaced by another arm of the cross

Identify the **NE quadrant** of the figure, no part of the isogyre will be in the FOV

Can now determine the optic sign in the same way as with a centred Optic Axis Figure:

Is the **g** ray the fast or slow ray?

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

## Uniaxial Flash Figure

- Mineral grain is oriented with the optic axis \_\_\_\_\_
- Grain will exhibit its \_\_\_\_\_ interference colour
- Interference figure is a broad, fuzzy cross

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

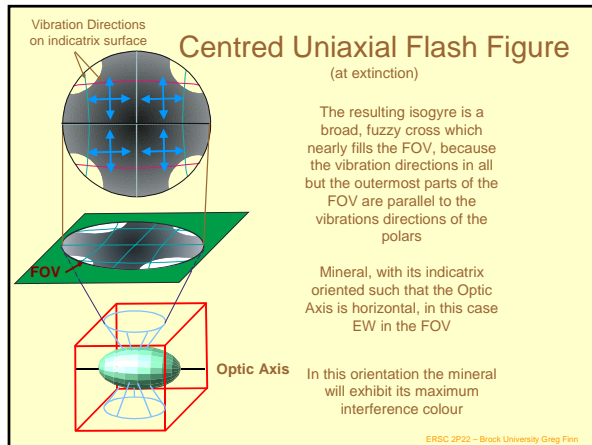

---

---

---

Vibration Directions on indicatrix surface

### Centred Uniaxial Flash Figure (at extinction)

The resulting isogyre is a broad, fuzzy cross which nearly fills the FOV, because the vibration directions in all but the outermost parts of the FOV are parallel to the vibrations directions of the polars

Mineral, with its indicatrix oriented such that the Optic Axis is horizontal, in this case EW in the FOV

Optic Axis

In this orientation the mineral will exhibit its maximum interference colour

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

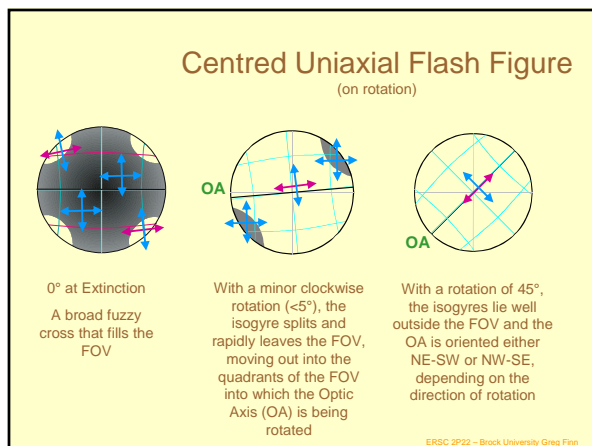

---

---

---

---

### Centred Uniaxial Flash Figure (on rotation)

0° at Extinction  
A broad fuzzy cross that fills the FOV

With a minor clockwise rotation (<5°), the isogyre splits and rapidly leaves the FOV, moving out into the quadrants of the FOV into which the Optic Axis (OA) is being rotated

With a rotation of 45°, the isogyres lie well outside the FOV and the OA is oriented either NE-SW or NW-SE, depending on the direction of rotation

ERSC 2P22 – Brock University Greg Finn

---

---

---

---

---

---

---

---

## Uniaxial Figures - Summary

- **Optic Axis Figure**
  - Section perpendicular to the c-axis (Optic Axis)
  - Lowest interference colour
  - Appears isotropic or nearly isotropic under crossed polars
- **Off-Centred Optic Axis Figure**
  - c-axis (Optic Axis) inclined to vertical
  - Only see one isogyre arm at a time, will sweep through the field of view
  - Intermediate birefringence therefore intermediate interference colour
- **Flash Figure**
  - c-axis (Optic Axis) is horizontal, parallel to the stage
  - Maximum interference colour

ERSC 2P22 – Brock University Greg Finn

Interpretation of Interference Figures							
Type of Figure	Orientation	Interference Colour	Orientation of figure for sign determination	Accessory effect for a positive mineral Gypsum Plate Quartz Wedge	Vibration direction observed	+	-
UNIAXIAL MINERALS							
These are distinguished from biaxial minerals by the failure of the centre of the isogyre cross to break as the stage is rotated, or if the centre of the cross is not visible, by the isogyres remaining parallel to the crosshairs. This distinction does not apply to the flash figure.							
<b>Centred Optic Axis</b> Isogyres form a black cross which does not split during rotation of the stage	Optic axis is vertical	Black, very low first order				Only is vibration direction observed in grain	
<b>Off Centred Optic Axis</b> Centre of cross displaced from centre of field. Vertical and horizontal isogyres alternately sweep across field, parallel to crosshairs.	Optic axis is inclined to vertical	Low to moderate					
<b>Flash Figure</b> Large diffuse black cross which breaks into four quadrants that disappear from the field after a 10 degree rotation of stage into quadrants of field of view occupied by the optic axis	Optic axis is parallel to microscope stage	Maximum colour for that grain		Not definitive to determine sign, however interference figure and accessory plate may be used to determine whether e ray is fast or slow.
